# Separation of Concerns in Denotational Semantics Descriptions 

Roberto S. Bigonha<br>Universidade Federal de Minas Gerais bigonha@dcc.ufmg.br

Fabio Tirelo<br>Google Inc ftirelo@google.com

Guilherme H.S. Santos<br>Universidade Federal de Minas Gerais guisousa@dcc.ufmg.br

#### Abstract

Denotational semantics is a powerful and elegant formalism for describing the meaning of programming language constructs, but it is used less than it should. Apparently, the difficulty of reading formal semantic definitions is inherent to the way they are organized. This paper presents a semantics definition style based on the concept of components in order to provide legibility to descriptions in this formalism. The idea is to remove context dependence from the semantic equations. Consequently, the equations in this style only specify the direct mapping from language constructs to their denotations by means of denotational components in an easy and readable way, and the details, such as context handling, are encapsulated away.

## Keywords

Denotational Semantics, Legibility, Modularity, Semantic Components

## 1. THE ROOTS OF ILLEGIBILITY

In the industry, programming languages are described by means of a formal presentation of their syntax based on context free grammars together with an informal description of their semantics. Even when a formal definition of the language is publicly available, it is rarely read by programmers and computer scientists.

According to P. Mosses[7], one of the reasons for this limited use of formal semantics in the industry is the difficulty most programmers and computer scientists have in dealing with the mathematical apparatus of formal definitions.

If Backus-Naur form has been established as a universal notation for defining programming languages syntax, formal semantics methods have never achieved similar success. Probably this is due to the fact that no formal semantics method has the simplicity of the syntactic formalisms, and also that, in denotational semantics, although the semantics of a language construct should depend only on the semantics of its immediate constituents, there are always, in the

[^0]semantic equations, explicit dependences on other elements, such as the construct's context.

Tirelo et alii[11] have identified that the context in which the meaning of a construct is defined can split in: (i) antecedents (ii) destination (iii) locality as shown in Fig. 1.

The antecedents of a construct's context comprises the effects of what has been executed priorly in the program. In general these effects are propagated to the construct by entities like store and enviroment. For example, the values previously assigned to variables are part of the context in which an expression is evaluated.

The destination of a construct provides the context to which the effects of its execution are to be sent. This is usually modelled by the notion of continuations. For example, in a statement sequence, the destination of the results produced by the execution of the first statement are the commands that follow it.

And the locality is the context given by the construct's enclosing structure in the abstract syntax tree. The semantics of the C break statement, for instance, depends on whether it occurs inside a loop or in a switch statement.

Figure 1: Context Dependence Model

In order to cope with all these facets of the context, the semantic equation of a construct must be provided with apropriate parameters, in addition to those that specify its constituents. The semantics specification requires that these context parameters be transmitted to the denotations of the construct's constituents and also to its destination. The need to explicitly deal with context produces an undesirable dependence relation among equations and the related domain apparatus in which they are defined, impairing their legibility.

Moreover, the abstraction mechanisms of $\lambda$-calculus, considered insufficient to properly encapsulate definition details
of semantic domains, aggravate even more the legibility issue [3, 6, 7, 12].
In summary, context dependence, the lack of appropriate modularization mechanisms and the need to always provide complete semantics definitions make them very intricate, and, thus, the legibility of formal descriptions of real size programming languages like C++ and Java become completely undermined.
The purpose of the work is to provide a method for organizing denotational semantics descriptions in order to enhance legibility. The method is based on removing the context dependence from all semantic equations and constructing a separate module of denotational components to encapsulate context details. This style of organizing definitions rescues the idea that the semantics of a construct only depends on that of its immediate constituents.

## 2. THE CLASSICAL STYLE

The formal description of the toy programming language Small, defined by M. Gordon [2], will be used to demonstrate the use of components and to highlight the improvement in legibility that can be achieved. The abstract syntax of Small is presented in Fig. 2. The equations and definitions in Fig. 3,4 e 5 are an adaptation from Gordon's original definition.

```

Figure 2: Abstract Syntax of Small

The domains defined in Fig. 3 intend to model imperative language whose expressions may have collateral effects and several types of errors may be flagged during program execution. Procedure and functions are limited to have just one parameter to simplify the presentation. Likewise, the definitions of binary operation ( 0 and of integer constants (B) are left unspecified.

Important domains are those modelling expression, command and declaration continuations (Ec, Cc, Dc), machine states (Store) and environments (Env). The continuation domains model the destination of the effects of executing a construct, the state represents an abstract structure to store values and the environment defines the meaning of names in the program. Environment and machine state model the
antecedents of a construct.

| Primitive Semantic Domains: |  |
| :---: | :---: |
| Num $=\{0,1,2, \ldots\}$ | - numbers n |
| Boolean = \{true,false\} | - booleans b |
| Loc $=$ Num | - locations l |
| Bv = Num + Bool | - basic values e |
| $\mathrm{Id}=$ domain of identifier | - identifiers I |
| Compound Semantic Domains: |  |
| Ans $=$ \{error, stop $\}+\operatorname{Rv} \times$ Ans | - answers a |
| $\mathrm{Rv}=\mathrm{Bool}+\mathrm{Bv}$ | - r-values v |
| File = Rv* | - files i |
| Dv = Loc + Rv + Proc + Fun | - denotable d |
| $\mathrm{Ev}=\mathrm{Dv}$ | - expressible e |
| $\mathrm{Sv}=\mathrm{Rv}+\mathrm{File}$ | - storable x |
| Env = Id $\rightarrow$ [Dv+\{unbound $\}]$ | - environments $r$ |
| Store $=$ Loc $\rightarrow$ [Sv+\{unused\}] | - stores s |
| Dc $=$ Env $\rightarrow$ Store $\rightarrow$ Ans | - continuation u |
| $\mathrm{Ec}=\mathrm{Ev} \rightarrow$ Store $\rightarrow$ Ans | - continuation k |
| Cc = Store $\rightarrow$ Ans | - continuation c |
| Fun $=\mathrm{Ec} \rightarrow \mathrm{Ev} \rightarrow$ Store $\rightarrow$ Ans | - fun values f |
| Proc $=\mathrm{Cc} \rightarrow \mathrm{Ev} \rightarrow$ Store $\rightarrow$ Ans | - proc values p |
| Denotation Domains: |  |
| $\mathrm{Pd}=$ File $\rightarrow$ Ans | - programs |
| Dd $=$ Env $\rightarrow$ Dc $\rightarrow$ Store $\rightarrow$ Ans | - declarations |
| Ed $=$ Env $\rightarrow$ Ec $\rightarrow$ Store $\rightarrow$ Ans | - expressions |
| Cd $=$ Env $\rightarrow$ Cc $\rightarrow$ Store $\rightarrow$ Ans | - commands |
| Semantic Functions: |  |
| $\mathcal{P}$ : Pro $\rightarrow$ Pd | - programs |
| $\mathcal{D}:$ Dec $\rightarrow$ Dd | - declarations |
| $\mathcal{R}: \operatorname{Exp} \rightarrow \mathrm{Ed}$ | - expressions |
| $\mathcal{E}: \operatorname{Exp} \rightarrow \mathrm{Ed}$ | - expressions |
| $\mathcal{C}: \mathrm{Com} \rightarrow \mathrm{Cd}$ | - commands |

Figure 3: Semantic Domains (adapted from [2])

Domain Dv is the domain of denotable values, with which Small identifiers can be associated in the environment. To keep the formulation simple, identifiers used in Small programs and their respective denotations are considered the same, i.e, I denotes elements of Ide and of Id. The context of its use should be sufficient to resolve this overloading.

Domain Sv is that of storable values which can be associated with locations in the machine states. The values passed to expression continuations belong to the domain Ev of expressible values. The basic values Bv represent booleans and numbers. The domain of program denotations Pd represents functions that model Small programs as a whole. Functions in this domain must deal with the program's input file, its initial context and produce the final answer of its execution.

The propagation of the semantic effects of Small constructions are modeled by the domains Dc, Ec and Cc of declaration, expression and command continuations, respectively.

Expression denotations are elements of domain Ed, command denotations are in Cd, and Dd is the domain of the declaration denotations.

The auxiliary functions in Fig. 4 implement a set of fundamental operations over members of semantic domains. Most of these functions follow the continuation style in order to be adhrent to the adopted model.

## 3. THE UNDERLYING IDEA

The proposed style of organizing denotational descriptions is inspired in Peter Mosses' concepts of components [8, 9, 10] that he has used to improve reusability of action semantics and structured operational semantics descriptions.
The proposed method basic idea is illustrated with the description of the if-then-else statement of Small, which is defined by the folowing equation extracted from Fig. 5:

```
\(\mathcal{C} \llbracket\) if E then \(\mathrm{C}_{1}\) else \(\mathrm{C}_{2} \rrbracket \mathrm{r} \mathrm{c} \mathrm{s}=\)
    \(\mathcal{R} \llbracket \mathrm{E} \rrbracket \mathrm{r}\) ( \(\lambda \mathrm{v}\) s.Bool? \(\mathrm{Cl}_{\mathrm{v}} \mathrm{s}\).
        cond \(\left(\mathcal{C} \llbracket \mathrm{C}_{1} \rrbracket \mathrm{r} \mathrm{c} \boldsymbol{s}, \mathcal{C} \llbracket \mathrm{C}_{2} \rrbracket \mathrm{r} \mathrm{c}\right.\) s) v\() \mathrm{v}\) s) s
```

This construct's context is defined by the enviroment $\mathrm{r} \in$ Env, the command continuations $c \in C c$ and by the machine state $\mathrm{s} \in$ Store.
The use of this context is fundamental to convey the desired meaning to the command, but it certainly impairs readability. Note that the context, represented by r, c and s is mentioned 18 times in the equation (1), and it would be nice to be able to cross it out.
This can be achieved by means of a Turner-like combinator [1], which produces equation (2):

```
C \if E then Cl else C2 \r c s =
    choice(\mathcal{E}\llbracketE\rrbracket,\mathcal{C}\llbracket\mp@subsup{\textrm{C}}{1}{}\rrbracket,\mathcal{C}\llbracket\mp@subsup{\textrm{C}}{2}{}\rrbracket) r c s
```

```
...... ...... ....... Programs
\(\mathcal{P} \llbracket\) program C】i \(=\mathcal{C} \llbracket \mathrm{C} \rrbracket \mathrm{r}_{0} \mathrm{c}_{0} \mathrm{~s}_{0}\)
    where \(r_{0}=\lambda I\).unbound
            \(c_{0}=\lambda\) s.stop
    \(\mathrm{s}_{0}=\lambda l\). unused) [i/input]
    N.B.: input Loc is a reserved location
....................Declarations....................

\(\mathcal{C} \llbracket \mathrm{E}_{1}:=\mathrm{E}_{2} \rrbracket \mathrm{r}\) c \(\mathrm{s}=\mathcal{E} \llbracket \mathrm{E}_{1} \rrbracket \mathrm{r}\left(\mathrm{Loc} ? \lambda l\right.\) s. \(\mathcal{R} \llbracket \mathrm{E}_{2} \rrbracket \mathrm{r}\)
                            ( \(\lambda \mathrm{v}\) s.update \(l \mathrm{c} \mathrm{v} \mathrm{s}) \mathrm{s})\) ) s
\(\mathcal{C} \llbracket\) output \(\mathrm{E} \rrbracket \mathrm{r} \mathrm{c} \mathrm{s}=\mathcal{R} \llbracket \mathrm{E} \rrbracket \mathrm{r}(\lambda \mathrm{e} .(\mathrm{e} . \mathrm{c} \mathrm{s})) \mathrm{s}\)
\(\mathcal{C} \llbracket\) if \(E\) then \(\mathrm{C}_{1}\) else \(\mathrm{C}_{2} \rrbracket \mathrm{r} \mathrm{c} \mathrm{s}=\)
    \(\mathcal{R} \llbracket \mathrm{E} \rrbracket \mathrm{r}\) ( \(\lambda \mathrm{v} \mathrm{s} . \operatorname{Bool}\) ? ( \(\lambda \mathrm{v} \mathrm{s}\).
            cond \(\left(\mathcal{C} \llbracket \mathrm{c}_{1} \rrbracket \mathrm{r} \mathrm{c} \mathrm{s}, \mathcal{C} \llbracket \mathrm{C}_{2} \rrbracket \mathrm{r} \mathrm{c}\right.\) s) v\() \mathrm{v}\) s) s
\(\mathcal{C} \llbracket\) while E do \(\mathrm{C} \rrbracket \mathrm{r} \mathrm{c} s=\mathrm{fix} \lambda \mathrm{f} . \mathcal{R} \llbracket \mathrm{E} \rrbracket \mathrm{r}\) (Bool?
    ( \(\lambda \mathrm{v}\) s.cond \((\mathcal{C} \llbracket \mathbb{C} \rrbracket \mathrm{r}(\lambda \mathrm{s} . \mathrm{f}\) r c s) \(\mathrm{s}, \mathrm{c}\) s) v\()\) ) s
\(\mathcal{C} \llbracket \mathrm{E}_{1}\left(\mathrm{E}_{2}\right) \rrbracket \mathrm{r} \mathrm{c} \mathrm{s}=\mathcal{E} \llbracket \mathrm{E}_{1} \rrbracket \mathrm{r}\left(\operatorname{Proc} ?\left(\lambda \mathrm{p} \quad \mathrm{s} . \mathcal{E} \llbracket \mathrm{E}_{2} \rrbracket \mathrm{r}(\mathrm{p} \mathrm{c}) \mathrm{s}\right)\right) \mathrm{s}\)
\(\mathcal{C} \llbracket \mathrm{C}_{1} ; \mathrm{C}_{2} \rrbracket \mathrm{r} \mathrm{c} \mathrm{s}=\mathcal{C} \llbracket \mathrm{C}_{1} \rrbracket \mathrm{r}\left(\mathcal{C} \llbracket \mathrm{C}_{2} \rrbracket \mathrm{r} \mathrm{c}\right) \mathrm{s}\)
\(\mathcal{C} \llbracket\) begin \(\mathrm{D} ; \mathrm{C}\) end \(\rrbracket \mathrm{r} \mathrm{c} \mathrm{s}=\)
        \(\mathcal{D} \llbracket \mathrm{D} \rrbracket \mathrm{r}\left(\lambda \mathrm{r}_{1} \mathrm{~s} . \mathcal{C} \llbracket \mathrm{C} \rrbracket \mathrm{r}\left[\mathrm{r}_{1}\right] \quad \mathrm{c} s\right) \mathrm{s}\)
```

Figure 5: Classical Semantics of Small (adapted from [2])
where the combinator choice is defined as:

$$
\begin{align*}
& \text { choice( } \mathrm{E}, \mathrm{C}_{1}, \mathrm{C}_{2} \text { ) r c s = } \\
& \text { Er ( } \lambda \mathrm{v} \text { s.Bool? ( } \lambda \mathrm{v} \text { s. }  \tag{3}\\
& \text { cond ( } \mathrm{C}_{1} \mathrm{r} \mathrm{c} \mathrm{~s}, \mathrm{C}_{2} \mathrm{r} \mathrm{c} \text { s) v) v s) s }
\end{align*}
$$

Note that the combinator parameters are solely denotations of the command's immediate constituents and the context. For clarity purpose, it is important to keep it that simple.
The next step is to abstract away the combinator definition from the description reader's eyes, placing it in a library of denotational components, and applying $\eta$ reduction to equation (2) that becomes:

```
C}\llbracket\mathrm{ if E then C Cl else C C \ = choice( }\mathcal{E}\llbracketE\rrbracket,\mathcal{C}\llbracket\mp@subsup{\textrm{C}}{1}{}\rrbracket,\mathcal{C}\llbracket\mp@subsup{\textrm{C}}{2}{}\rrbracket
```

This equation reveals that the semantics of Small if-thenelse command is such that the value of E is to be evaluated
first, and if its value is true, the execution proceeds with command $\mathrm{C}_{1}$, otherwise command $\mathrm{C}_{2}$ is to be executed.

Hopefully, to have this level of understanding of the meaning of the defined construction it is enough to know the choice's interface, and there is no need to know details of the definition of this combinator.

To generalize this structuring process, consider the semantics $h$ of a generic construct $A$ defined in a context $\mathbf{z}$ :

$$
\begin{aligned}
& A \rightarrow r_{0} B_{1} r_{1} B_{2} \ldots B_{n} r_{n} \\
& h: A \rightarrow \text { Context } \rightarrow \text { Ans } \\
& h \llbracket r_{0} B_{1} r_{1} B_{2} \ldots B_{n} r_{n} \rrbracket z=g\left(h_{1} \llbracket B_{1} \rrbracket, h_{2} \llbracket B_{2} \rrbracket, \ldots, h_{n} \llbracket B_{n} \rrbracket, z\right)
\end{aligned}
$$

The functions $h_{i}$, for $0 \leq i \leq n$, give the semantics of $A$ 's constituents.
This semantics modelling follows the mapping structure displayed in Fig. 6, in which function $g$ combines the semantics of the immediate constituents of A to produce its meaning. The function $g$ does not show any dependency on the terminal symbols that occur on the right hand side of the production defining $A$. Only the nonterminals take part in the formulation. This means that each right hand side must imply in a new $g$, i.e., the dependence on terminal symbols are forged into the structure of $g$. This is so because although passing denotations of terminal symbols directly to $g$ could hinder legibility, there are situations in which it may contribute to component reuse.

Figure 6: The Semantic Model
To encapsulate the flow of context information, consider the generic combinator $K$, defined as:

$$
K\left(d_{1}, d_{2}, \ldots, d_{n}\right) z=g\left(d_{1}, d_{2}, \ldots, d_{n}, z\right)
$$

Observe that $K$ only operates over the denotations of the immediate constituents of $A$, preserving the meaning provided by $g$. Using $K$ to rewrite the definition of $h$ produces:

$$
h \llbracket r_{0} B_{1} r_{1} B_{2} \ldots B_{n} r_{n} \rrbracket z=K\left(h_{1} \llbracket B_{1} \rrbracket, h_{2} \llbracket B_{2} \rrbracket, \ldots, h_{n} \llbracket B_{n} \rrbracket\right) z
$$

which may be simplified to:

$$
h \llbracket r_{0} B_{1} r_{1} B_{2} \ldots B_{n} r_{n} \rrbracket=K\left(h_{1} \llbracket B_{1} \rrbracket, h_{2} \llbracket B_{2} \rrbracket, \ldots, h_{n} \llbracket B_{n} \rrbracket\right)
$$

It is recommended that each equation use just one combinator, avoiding enticing combinator compositions so as to rescue the central idea of the denotational semantics formalism that the meaning of a construct only depends on the meanings of its immediate constituents.

To achieve legibility, discipline and standardization are mandatory. So it seems reasonable to require that all combinators like $K$ must have the standard type:
$K: D_{1} \times D_{2} \cdots \times D_{n} \rightarrow$ Context $\rightarrow$ Ans, for $n \geq 0$
where $D_{i}$, for $0 \leq i \leq n$, are domains of denotations or of special values associated with the production.

Typically, the parameters of a combinator should be only denotations. However, in order to favour reuse of components and yet preserving legibility, sometimes it is convenient to pass to the combinator especial values to determine some specific behavior, instead of writing several similar functions. The need for this arises when more than one production have the same nonterminals on their right hand sides, being distinguished only by the terminal symbols involved.

This process of encapsulating context should be applied to the semantic equations of all constructs in the language, producing a clean set of mapping, such as that of Fig. 10, which is much more legible than its counterpart in Fig. 5.

The claim is that to understand the component-based denotational semantics description of a given programming language all that is required is to know the interface of the used components, without any concern regarding details of their definitions.

Due to the continuous evolution of programming languages, it would be interesting to have a library of generic components that allows easy incorporation of new constructs to the languages. The more generic are the components the better will be the library, because the same components could be used to define many languages.

The challenge is to find a set of generic components capable of modelling the semantics of the most important constructs of popular languages, thus reducing the need to define new components whenever defining new programming languages. However, for space reasons, this problem is not addressed in this paper.

## 4. COMPONENT-BASED SEMANTICS

The information regarding context, i.e., environment, store and continuations, only appears on the definition of the main equation of the description, the definition of $\mathcal{P} \llbracket$ Program $\mathrm{C} \rrbracket$, which gives the meaning of Small programs. This is the moment the context should be properly and explicitly initialized, and from this point on, it flows implicitly throughout the description.

Thus, the equation for $\mathcal{P} \llbracket$ Program C $\rrbracket$ in Fig. 5 should not be object of componentization and, without modification, it becomes part of the component-based description of Fig. 10

The componentization process consists in creating new components to replace the right hand side of the Small semantic equations. In case of Small declarations, these components are cbinding, fbinding, pbinding, vbinding e elaboration, which show how the denotations of the constituents of each declaration are to be combined to build the semantics of the respective construct. The resulting semantic equations from the componentization of Small declarations are presented in Fig. 7, and transported to Fig. 10.

In the componentization process, the type of the components must keep conformity to the structure defined in section 3: either the components parameters are denotations of constructs, e.g. operation and pcall or they are basic values, such as in value, association and read in Fig. 8.

The resulting component-based definition of Small is in Figura 10, which is the reference text for the semantics of the language Small.

The other equations, whose details can be abstracted by the reader, are presented in Fig. 2, 3, 4, 7, 8 and 9.

```
D|const I = E|r u s = cbinding(I,\mathcal{R}|E|)r u s
where
    cbinding:Ide }\times\mathrm{ Ed }->\mathrm{ Env }->\mathrm{ Dc }->\mathrm{ Store }->\mathrm{ Ans
    cbinding(I,d)r u s = d r(\lambdav s.u[v/I]s)s
D}\llbracket\operatorname{var}I=E\rrbracketr u s = vbinding(I,\mathcal{R}\llbracketE\rrbracket)r u 
where
    vbinding:Ide }\times\mathrm{ Ed }->\mathrm{ Env }->\mathrm{ Dc }->\mathrm{ Store }->\mathrm{ Ans
    vbinding(I,d) r u s =
                d r(\lambdav s.ref(\lambdal s.u[l/I]s)v s)s
```

```
where
    pbinding:Ide }\times\mathrm{ Ide }\times\textrm{Cd}->\textrm{Env}->\textrm{Cd}->\mathrm{ Store }->\mathrm{ Ans
    pbinding(I,I I,d) r u s =
        u((\lambdac e s.C \C||r[e/I I ]c s)/I)s
D \llbracketfun I(I I ; E)\rrbracketr u s = fbinding(I, I 
where
    fbinding:Ide }\times\mathrm{ Ide }\times\mathrm{ Cd }->\mathrm{ Env }->\mathrm{ Ed }->\mathrm{ Store }->\mathrm{ Ans
    fbinding(I,I I,d) r u s =
                u((\lambdak e s.\mathcal{E}\llbracketE|r[e/I I k s)/I)s
D \llbracket\mp@subsup{D}{1}{}; D D \ r u s = elaboration(\mathcal{D}\llbracket\mp@subsup{D}{1}{}\rrbracket,\mathcal{D}\llbracket\mp@subsup{D}{2}{}\rrbracket) r u s
where
    elaboration:Dd }\times\mathrm{ Dd }->\mathrm{ Env }->\mathrm{ Dc }->\mathrm{ Store }->\mathrm{ Ans
    elaboration(d}\mp@subsup{d}{1}{},\mp@subsup{d}{2}{})r u s =
        d
```

## 5. RELATED WORK

The component-based style for denotational semantics is a complementary approach to other proposed solution to the legibility problem. For instance, the incremental definition style of Tirelo at alli[11], which is based on the linguist concept of vagueness can benefit from the use of components. In the incremental approach details are added stepwisely to a simpler definition by means of a mechanism named denotation transformation. The use of components may help separating concerns, which is very important to facilitate the integration of new elements to the definition.

Another important attempt to solve the legibility problem is the monadic semantics proposed by Moggi $[4,5]$. This proposal also removes the context information from the equations and, consequently, reaches high level of modularity. However, monad semantics requires complex and intricate monad transformation operations. Component-based semantics are much simpler, they can encapsulate fundamental concepts in a way easy to use.

Apparently P. Mosses [8] has avoided the use of denotational semantics as the basis for a technique based on components due to the low legibility caused by the explicit use of context information. The present proposal overcomes these difficulties.

A comparison with other approaches to formal semantics, such as action semantics and structured operational semantics, is not addressed at this moment because the focus of this work is the improvement of the legibility of denotational semantics, not to make it supersede other models. Each formal method has its proper niche, in which it produces better results. Component-based denotational semantics just brings value to this formalism.

## 6. CONCLUSIONS

This work proposes an style to organizing denotational se-

Figure 8: Expression Componentization
mantics description, inspired in P. Mosses's work [8, 9, 10] on action and structured operational semantics, in order to produce noticeable improvement in formal definition legibility.

A judicious use of denotational components permits the removal of context dependence from the presentation of semantic equations, making them more legible. To this purpose, the component signatures are standardized and the flow of context information is encapsulated within these components.

The result is that semantic definitions are reduced to a mapping from abstract syntax constructs to their denotations expressed as a combination of denotational components.

The encapsulation of fundamental and intricate concepts of programming languages may contribute to make formal semantics popular and turn the descriptions of the semantics of sizable programming languages readable by programmers and computer scientists.
The next step is to standardize the notion of context and to define a library of generic components that are applica-
